

Collateral Damage: Human and Physical Capital in Consumer Lending

Mark Garmaise, Mark Jansen, and Adam Winegar*

June 2022

ABSTRACT

We study the relative importance of asset-backed lending (ABL) and cash flow-based lending (CFBL) in auto finance. We find that negative durability shocks generated by vehicle discontinuations lead to increased loan-to-value ratios and down payments. These results are consistent with an ABL+CFBL model in which CFBL is particularly important for low-income consumers. After default, two-thirds of lender recoveries arise from the vehicle and one-third come from the borrower personally. The heavy use of CFBL by low-income consumers suggests that their relative credit access may decline with the securitization-driven rise of ABL.

1. Introduction

The U.S. automotive lending market has expanded dramatically over the past 10 years and is now very large (\$1.3 trillion in loans outstanding as of 2021), as shown in Figure 1. The dominant description of the auto financing market emphasizes the role of physical collateral in securing the claims of lenders (Assunção et al., 2014; Argyle et al., 2020; Ratnadiwakara, 2021). This is undoubtedly correct, and auto lenders consider carefully the liquidation value of vehicles in deciding whether and on what terms to extend credit. In this paper, however, we highlight the use by creditors of cash flow-based lending (CFBL) supported by a car buyer’s income (i.e., her human capital) that supplements their reliance on asset-based lending (ABL) linked to the physical collateral value of the vehicle. In an empirical analysis motivated by a simple theoretical framework, we show that CFBL (along with ABL) plays a key role in explaining several features of the car loan market.

While the claim that CFBL is important for auto lending is perhaps uncontroversial, our central interest is in determining which types of buyers rely most heavily on CFBL versus ABL. In particular, we focus on analyzing the relative importance of CFBL and ABL for the auto credit provided to low-income borrowers. Access to auto financing is particularly valuable in the U.S., where vehicle ownership is often critical for employment opportunities and mobility (Gurley and Bruce, 2005; Baum, 2009; Gautier and Zenou, 2010; Moody et al., 2021). Recent empirical evidence from Brazil corroborates the finding that vehicular access increases formal employment rates and salaries (Doornik et al., 2021). Ensuring the ability of low-income borrowers to borrow to purchase cars is therefore important for a broad set of policy goals. A clear understanding of the parts played by CFBL and ABL in facilitating vehicle financing thus serves two functions. First, it provides insights into which financial innovations are most likely to aid low-income auto credit borrowers. Second, given that CFBL is probably more cyclical, it helps in predicting how different car purchasers will be affected by economic fluctuations.

ABL and CFBL are clearly intertwined, and it is a challenge to empirically assess the importance of CFBL for auto finance for various types of borrowers; car loan contracts do not explicitly assign weights to the ABL and CFBL components of the financing. To distinguish these two types of lending, we develop a theory showing that they respond differently to changes in the durability of the underlying physical asset. Specifically, in an ABL-only model a decrease in durability decreases the loan-to-value (LTV) ratio (Hart and Moore, 1994) and also decreases the borrower's down payment (Rampini, 2019), as the asset becomes both less capable of supporting debt and less expensive. In a model of ABL and CFBL (i.e., an ABL+CFBL model), by contrast, a decrease in durability may increase both the LTV and the down payment. LTV values may be higher for less durable assets because low-income borrowers can rely on CFBL to finance non-durable assets with very low collateral values, thereby generating high LTV ratios. Down payments may be higher for less durable assets because they are purchased by low-income borrowers who have little future income to pledge to support borrowing today. We show that it is an implication of the ABL+CFBL model that if non-durable assets have higher LTVs and down payments, then it must be the case that low-income borrowers depend more heavily than high-income borrowers on CFBL. The divergent predictions of the two models provide an opportunity to empirically assess the importance of CFBL for auto lending for different kinds of borrowers.

Testing these differing hypotheses requires a shock to durability. While cars may vary in their durability for a number of reasons (e.g., manufacturing excellence, age, miles driven, etc.), these sources of variation are also associated with differences along many other dimensions (e.g., quality of driving experience, amenities and options). We wish to identify the pure effect of a change in durability, so we seek shifts in durability that do not have an impact on current quality of the vehicle. We utilize model and make discontinuations on existing cars as shocks to durability. In the last twenty-five years 825 car models and eight car brands have been discontinued. Repair costs relative to vehicle value are of first-order importance in keeping a car on the road (Insurance Networking News, November 15, 2015) and

discontinuation plausibly reduces vehicle durability of existing cars due to concerns about future parts and service expertise (Titman, 1984).¹ The inability to get replacement parts and increased servicing costs is frequently cited as a concern following the discontinuation of a car brand or model.²

We begin our empirical analysis by showing that discontinuations do indeed reduce durability. Under both the ABL-only and ABL+CFBL models less durable assets have lower prices, lower residual values and are purchased by less-wealthy consumers. We show that after the announcement of discontinuation, car values fall by about \$291 or approximately three percent of the value when new. We further find that default recoveries (the value the lender receives from the vehicle liquidation after default over the vehicle’s wholesale value at origination) decline by roughly 1.7 percentage points after discontinuations. We also show that discontinued cars are more likely to be purchased by low-income borrowers. These findings provide clear evidence under both ABL and ABL+CFBL theories that discontinued vehicles have reduced durability and lower liquidation values. Both models also predict that, if their residual values are sufficiently low, then discontinued vehicles will be financed at lower price-to-income (PTI) ratios, and we find that to be true in the data as well.

All of our empirical tests hold fixed the model-vintage year of the vehicle (and include dealer and corporate parent-transaction year fixed effects), so we are effectively comparing the same model-vintage year vehicle before and after a discontinuation announcement, while controlling for any changes at the corporate parent level and any dealer effects. While it is not a formal prediction of our stylized models, we further find that auto loans have shorter maturities after discontinuations, which supports the contention that they have reduced

¹While many internal components (e.g., transmission components) can be interchangeable across makes within the same car family (e.g., a Chevrolet part can be used in a GMC), it is not universally true for all components and it is especially problematic for external components (e.g., driver’s side panels), which are mostly likely to be damaged in a collision. Moreover, even if third-party suppliers provide these non-interchangeable components, they will generally be more expensive due to their specialized nature.

²For instance, a 2001 article around the announcement of the discontinuation of Oldsmobile notes “There is no question they’re going to take a serious hit in resale value. Anyone who buys an Oldsmobile has to understand that unless they keep it until it’s dead, it’s not going to be worth much.”

durability.

Discontinuation is a deliberate choice of the manufacturer, but it is not under the direct control of other auto market participants. Buyers, sellers and third-party financiers likely assign some probability to a possible future model discontinuation, but its actual occurrence (i.e., with certainty) must represent adverse news. Moreover, we find no evidence of increasing anticipation before the announcement; there is no observable pre-trend in vehicle price or LTV before discontinuation. For auto buyers, sellers and lenders, discontinuations appear to cause an unanticipated negative shock to durability.

We assess the relative importance of CFBL for high- and low-income borrowers by tracing the effects of discontinuation-driven durability shocks on LTV ratios and down payments. First, we show that discontinuation causes an increase of two percentage points in LTV ratios. This is a result that emerges in an ABL+CFBL setting if low-income borrowers make greater use of CFBL. If high-income borrower rely more heavily on CFBL (or if only ABL lending is available), by contrast, the lower liquidation values produced by a discontinuation should lead to lower LTV ratios, which we do not find.

Second, we show that down payments are approximately \$92 higher after discontinuations (a 9% increase relative to the mean). A post-discontinuation increase in down payments may occur in an ABL+CFBL model if future income is sufficiently pledgeable. Low-income consumers are forced to purchase the asset with a larger down payment, as their low future income does not allow them to borrow a large amount today. The higher down payments for discontinued vehicles that we document empirically offer additional support for the ABL+CFBL model. In an ABL-only model, the lower price of a less-durable asset should lead it to be purchased with a lower down payment, which we do not observe.

In the ABL+CFBL model, lenders partially support their debt with a claim on the borrower's future income. In the event of default, do auto lenders actually make personal recoveries aside from the proceeds from vehicle repossession as this model predicts? We find that they do. For our sample of defaulted loans, we show that the average proceeds from the

sales of repossessed vehicles are \$3,722 and the average cash recovery from the borrower is \$1,827. This indicates that in default physical assets and personal borrower resources supply 67% and 33%, respectively, of the total recovery proceeds.

Our results showing higher LTVs and down payments for discontinued vehicles support an ABL+CFBL model in which low-income borrowers make relatively greater use of CFBL. We offer an additional test of this theory by analyzing post-default recoveries. We show that in the event of default, discontinued vehicles have physical collateral recoveries that are \$585 lower. This would be expected under both the ABL and ABL+CFBL models. What is more surprising, however, is that personal default recoveries are \$287 higher for discontinued cars.

In fact, conditional on default, we find that after discontinuation there is a 6.8 percentage point increase in the probability that there will be a personal default recovery. Discontinued cars are less expensive and are purchased by lower-income borrowers, and yet we find that these purchases are markedly more likely, in the event of default, to result in a personal recovery. This perhaps counter-intuitive finding is rationalized by the ABL+CFBL model. The lower-income borrowers who purchase less durable assets rely more heavily on CFBL; given the low collateral value of these vehicles, if default occurs lenders seek personal recoveries.

Both the ABL and ABL+CFBL models recognize the importance of asset-backed financing. Thus, underlying each of these theories is the argument that a key value of collateral lies in its providing an avenue for the lender to recoup potential losses after default. This theme has been explored in an influential theoretical literature (Bernanke and Gertler, 1989; Hart and Moore, 1994, 1998; Rampini and Viswanathan, 2010, 2013; Rampini, 2019; Demarzo, 2019) and has been extensively validated in empirical tests (Benmelech et al., 2005; Benmelech, 2009; Gan, 2007; Chaney et al., 2012; Cerqueiro et al., 2016; Jahan, 2020; Li and Tsou, 2020; Ioannidou et al., 2022). The CFBL-specific component of lending, by contrast, is tied to the profit or income generated by the borrower (Dewatripont and Tirole, 1994; Holmstrom and Tirole, 1997).

In the corporate setting, large and profitable firms have been shown to make extensive use

of CFBL, while small and less-profitable firms depend almost exclusively on ABL (Lian and Ma, 2021). Consistent with these results, more resource-constrained and riskier firms are more likely to use collateral to support their borrowing (Leeth and Scott, 1989; John et al., 2003; Jimenez et al., 2006). By contrast, however, we show in the consumer auto loan market that CFBL is especially important for low-income borrowers. We argue that these divergent findings arise from the fact that small firms may be terminated and abandoned, which discourages CFBL. For defaulting natural persons the abandonment option is much more costly (as bankruptcies are reflected for at least seven years on credit reports), and it is often feasible for creditors to make CFBL collections from them in the form of wage garnishments and long-term bankruptcy payments.

As described above, our empirical findings are best explained by a ABL+CFBL model in which high-income borrowers make greater use of ABL while low-income borrowers depend to a greater degree on CFBL. A shift in financing markets that promotes ABL and disfavors CFBL is therefore likely to offer disproportionate benefits to wealthy consumers. In the post-financial crisis period, there has been a dramatic expansion in the securitization of collateralized assets such as equipment relative to the securitization of cash flow-based debt such as credit card receivables and student loans. Our analysis suggests that this change in securitization markets should facilitate auto lending especially for high-income borrowers, and we indeed observe that wealthier borrowers have come to account for an increasing proportion of car loan financing.

Our results indicate that innovations that reduce the cost of monitoring borrower incomes (e.g., automated data links to borrower bank accounts) will likely promote the provision of financing via CFBL to lower-income auto purchasers. Our findings also make clear that, given the cyclical nature of CFBL, vehicle lending to constrained borrowers is likely to decline disproportionately during recessions. These points may be helpful in providing guidance to ensure that credit markets serve, to the maximum extent possible, to protect the relative financial access of the poor.

2. Theoretical Framework

To illustrate the effects of a durability shock on the consumer financing of asset purchases, we provide a simple model of financing. In this section we outline the model and describe the main results; the technical details are supplied in the Appendix.

We assume that there are two types of consumers with either high or low income. Consumers can purchase either durable or non-durable assets from sellers (i.e., car dealerships) who charge a markup on sales. Both types of assets have a current period price and a residual value next period. We make the following assumption:

Assumption 1.

- a) *Durable assets have a higher price than non-durable assets in the current period.*
- b) *Durable assets have a higher ratio of residual value to current period price than non-durable assets.*

Lenders provide financing at competitive rates. Consumers prefer current over delayed consumption. We study two models. In Model ABL, the only source of financing for consumers is asset-backed lending secured by collateral. The collateralized lending is subject to limited pledgeability. This environment is analogous to that examined in Rampini (2019). In Model ABL+CFBL, consumers have access to both asset-backed lending and to cash flow-based lending. Cash flow-based lending is guaranteed by the consumers' income.

We focus on the interesting region of the parameter space by assuming that high-income consumers can afford the durable good if they borrow to their maximum feasible limit but that low-income consumers can only afford the non-durable asset. We further presume that the durable asset is more attractive than the non-durable asset to unconstrained borrowers. This generates the following result for both models.

Result 1. In Models ABL and ABL+CFBL:

- a) *In equilibrium high-income borrowers purchase the durable good while low-income borrowers purchase the non-durable good.*

b) If the residual value of the non-durable good is sufficiently low, then the payment-to-income ratio is lower for low-income borrowers purchasing the non-durable asset than it is for high-income borrowers purchasing the durable asset.

Result 1a follows immediately from the assumed attractiveness of the durable good and the constraints faced by low-income borrowers. Result 1b arises from the fact that the promised payment for the non-durable good depends at least in part on its future residual value in both models ABL and ABL+CFBL. If this future residual value is very low, then the future payment must also be low.

We now consider the implications of Model ABL for the contrasting financing patterns of high- and low-income borrowers.

Result 2. In Model ABL:

a) The LTV ratio is lower for low-income borrowers purchasing the non-durable asset than it is for high-income borrowers purchasing the durable asset.

b) The down payment is lower for low-income borrowers purchasing the non-durable asset than it is for high-income borrowers purchasing the durable asset.

These findings echo the results in Rampini (2019). Result 2a follows from the fact that the LTV of the loan is determined by the ratio of the residual value to the current period price, which is higher for the durable good. Low-income borrowers who purchase the non-durable asset therefore have a lower LTV. In the ABL model, the down payment is higher for the durable good: as durability increases, so does the collateral value, but the increase in the collateral value is less than one-for-one as pledgeability is limited. Low-income borrowers can only afford the non-durable asset, so they offer lower down payments, as described in Result 2b.

Model ABL+CFBL adds a new source of financing: cash flow-based lending that is secured by a claim on consumers' future income that may be pledged to lenders. Mechanisms for securing future income could include wage garnishment or other lender claims that have recourse to borrower wealth other than the asset in question. Model ABL+CFBL yields the

following implications for borrower financing.

Result 3. In Model ABL+CFBL:

a) If income is sufficiently pledgeable and the difference in income between high- and low-income borrowers is not too large, then the LTV ratio is higher for low-income borrowers purchasing the non-durable asset than it is for high-income borrowers purchasing the durable asset.

b) If income is sufficiently pledgeable and the difference in income between high- and low-income borrowers is sufficiently large, then the down payment is higher for low-income borrowers purchasing the non-durable asset than it is for high-income borrowers purchasing the durable asset.

When cash flow-based lending is available, all consumers pledge their entire future income as security for the loan in order to borrow as much today so as to maximize current period consumption. If the ratio of low income to high income is reasonably high and income is sufficiently pledgeable, then low-income borrowers can borrow a large amount relative to the lower price of the non-durable good. This yields Result 3a.

The intuition for Result 3b is that income must be sufficiently pledgeable for high-income borrowers to reduce their down payments by offering a large future income-based payment. Both high- and low-income borrowers pledge their future incomes as security for cash flow-based lending, but low-income borrowers have less to pledge. As a result, as long as the difference in income between the two types of borrowers is sufficiently large, then low-income borrowers receive smaller cash flow-based loans and therefore must supply a larger down payment to purchase the asset.

Contrasting Results 2 and 3 shows that higher LTVs and down payments for low-income borrowers do not occur in Model ABL but may emerge in Model ABL+CFBL. (There are parameters that simultaneously satisfy the conditions of Results 3a and 3b). The following implication arises from the ABL+CFBL model.

ABL +CFBL Model Implication. If

a) The LTV ratio is higher for the non-durable asset

and

b) The down payment is higher for the non-durable asset

then

i) Income must be sufficiently pledgeable

and

ii) Low-income borrowers must rely relatively more heavily than high-income borrowers on CFBL.

It is clear from Results 2 and 3 that higher LTVs and down payments for low-income borrowers can only arise in models with CFBL (i.e., if income sufficiently pledgeable). Asset-based LTVs are higher for the durable good, as shown in Result 2, so higher LTVs for the non-durable good purchased by low-income borrowers require that those borrowers make heavy use of CBFL.

3. Data

To explore the role of asset durability on consumer financing, we examine loan terms offered from a large independent automotive indirect-finance company.³ The data include all loans that were purchased by the firm in 44 states between the early 1990s and 2021. In total, we observe key features of 291,493 loans that were originated at 3,929 dealerships located in 1,860 U.S. ZIP codes as described in Table 1, Panel A.⁴

The breadth and detail of our data distinguish our study from previous work. More specifically, we observe loan characteristics (e.g., purchase price and down payment) that are typically unavailable in aggregate data. For example, Experian Autocount data does not measure down payments and sale prices, limiting the construction of collateral measures.

³This firm is not one of the captive auto lenders studied by Benmelech et al. (2017) and Benetton et al. (2021).

⁴The raw data include approximately 343,000 loans. We exclude loans with incomplete origination data.

We also observe the price at which each loan is sold by the dealer to the lender, a value that may capture some otherwise unobservable loan or borrower attributes.

Table 1 presents summary statistics of the buyer, loan, and vehicle characteristics that were observable to the dealer at the time of origination for all loans in the sample where we observe complete origination data. In our sample, the median vehicle is two years old and has approximately 36,750 miles when sold. The median vehicle has a value of \$12,975, and the median down payment is \$700 (roughly 5% of the vehicle’s value). The median loan in our sample has a term of 72 months (6-years) and an APR of approximately 19.5%. Note the higher APR reflects that the borrowers in the sample are subprime—the median reported credit score is approximately 530, with roughly 30% of borrowers having a reported bankruptcy (chapter 7 or 13) within seven years of loan origination.

[Table 1 ABOUT HERE]

4. Discontinuations

4.1. *Background*

In order to causally identify the impact of durability on financing, we require a source of exogenous variation in asset durability. Moreover, to separate any general effect of durability from other technological shocks in the time series (e.g., financial engineering or digital processing of applications), we require a shock that affects only some vehicles but that still allows for controls for vehicle age and manufacturer, and model, and the year the vehicle was sold. Ideally, we would randomly assign similar vehicles different durability. While this may not be feasible, we can take advantage of shocks to existing vehicles that affect their future resale value and durability. Specifically, we utilize the discontinuation of makes and models of vehicles as a source of exogenous variation in vehicle durability in our data.

Importantly, this shock does not affect the current quality of a used car because no component of the car changes. In this sense the shock is only forward looking for future resale values of existing cars. Prior to discontinuation, the car is made in the same factories with the same materials. Moreover, by comparing car prices prior to discontinuation to the same model and year of car post-discontinuation, we can hold constant the car quality and use vehicles that were not shocked to control for the but-for depreciation curve.

One concern with this shock is that the decision to discontinue a make and model of car by the firm is an endogenous decision and there are many reasons a car manufacturer may choose to do so. For instance, a car manufacturer may choose to cut less profitable models during times of financial distress. However, in our specifications we can directly control for the parent car company and thus can compare cars of similar quality within the same car manufacturing family. Thus, any effect on durability due to potential future bankruptcy, as noted in Titman (1984) and shown to be empirically important in Titman and Wessels (1988) and Hortaçsu et al. (2013) among others, should affect all cars made by that manufacturer. Additionally, in several of cases the discontinuation happened when the auto manufacturer was not under financial distress. Moreover, by comparing pre-trends of the vehicles, we can plausibly detect any movements in the resale or depreciation value of the vehicles prior to the shock.

4.2. *Discontinuation Shocks*

Among the 825 discontinued models, we identify 209 instances in which the manufacturer decides to maintain the make of the car (e.g., Chevrolet) but discontinues a specific model (e.g., Chevrolet Monte Carlo), and the model appears in our loan data.⁵ We supplement these model discontinuations with eight discontinuations of major US car brands (i.e., makes) during our sample period. A list of discontinued models, discontinued makes and

⁵More than half of the discontinued models that are discontinued include low volume production vehicles such as the Aston Martin Vantage GT and the Ferrari 248

discontinuation years is provided in the Appendix in Table IA.1 and Table IA.2.

4.3. Empirical Methods

We use a difference-in-difference (DiD) approach to test the effect of our shock to depreciation. Specifically, for a transaction i , of model j , with dealer d , during period t , we run the following regression:

$$Y_{i,j,d,t,v} = \tau_t + \iota_{j,v} + \xi_d + \beta X_{i,j,d} + \phi_{j,t} \text{Treated}_{j,t} + \epsilon_{i,j,d,t}, \quad (1)$$

where Y is an outcome such as vehicle price or financing term, τ is a transaction year fixed effect, ι is a car model x vintage year fixed effect, ξ is a dealer fixed effect, X are a series of vehicle, borrower, and dealer controls, and Treated is an indicator if the make of model j has been discontinued prior to time t . Thus, in the cross-section we are comparing cars within the same period, absorbing any non-time varying attributes related to the specific model, and dealer. In all specifications we cluster by make.⁶

In additional specifications we include interactions of the fixed effects including the car make’s parent company x transaction year fixed effects ($\phi_{j,t}$). Thus we are also absorbing any effects related to the financial condition of the parent company at the time of the transaction. Importantly, this isolates general effects that would apply to all makes of a given parent company (e.g., GM during the 2008-2009 Global Financial Crisis).

⁶Several recent papers raise concerns of differential treatment timing in difference-in-difference regressions and raise the spectre of resulting bias when using higher dimensional fixed-effects if there is expected treatment effect heterogeneity (Callaway and Sant’Anna, 2021; Baker et al., 2022). We note several features of our analysis that should alleviate such concerns. First, we drop all observations where the vehicle age exceeds seven years. This reduces the potential for long-run effects to drive the results and for previously discontinued vehicles to act as future controls. Second, we note that 83% of our observations are never treated, reducing the likelihood of negative weights (Goodman-Bacon, 2021). Finally, we repeat our baseline specifications using the stacked regression approach of Gormley and Matsa (2011) and Cengiz et al. (2019), and find similar results.

5. Results

5.1. *Discontinuation Shock and Durability*

We propose to use the model and brand discontinuations described in Section 4 as a shock to vehicle durability. Parts availability and servicing expertise for discontinued vehicles are likely to degrade more quickly than for other vehicles. From the perspective of the theoretical framework described in Section 2, this suggests that discontinuation may be viewed as a shock that reduces the durability of a car.

We begin by empirically assessing the impact of discontinuation on durability. Assumption 1a in Section 2 asserts that durable assets should have higher prices. If discontinuation reduces durability, then it should reduce the vehicle price. We test this implication by estimating equation (1) and regressing a vehicle’s scaled price on a post-discontinuation indicator, model-vintage year fixed effects, dealer fixed effects and corporate parent-contract year fixed effects. Our use of model-vintage year fixed effects allows us to contrast vehicles of the exact same model and vintage year before and after discontinuation. Dealer fixed effects control for any differences among dealers. Corporate parent-contract year fixed effects remove any impacts that influenced the corporate parent. It is certainly plausible that corporations that discontinue a make or model may differ from those that do not. For example, it could be that corporate parents that discontinue a make or model may have weaker balance sheets and may therefore be less capable of guaranteeing future warranties. The corporate parent-contract year fixed effects control for any impacts of this kind. Taken together, this complement of fixed effects (which we refer to as the standard set of fixed effects) isolates the impact of discontinuation itself on the specific model that will no longer be manufactured.

We find, as shown in the first column of Table 2, that discontinued vehicles experience a drop in wholesale value of \$299.2 (t -statistic=-2.60). This is consistent with the claim that discontinuation reduces durability: less durable vehicles are less appealing to consumers

and should trade for lower values. Including controls for borrower income and credit score, indicators for prior borrower chapter 7 or chapter 13 bankruptcy filings and an indicator for borrower homeowner status leaves the qualitative finding unchanged, as shown in the second column of Table 2. Including a control for vehicle mileage yields the result that discontinuation reduces wholesale prices by \$290.5 (t -statistic=-2.64).

As a second measure of vehicle value we consider the scaled price, which is defined as the vehicle wholesale value divided by the average wholesale value of the given vehicle model and vintage when new. We show in the fourth column of Table 2 that the scaled price is 3.89 percentage points lower (t -statistic=-4.59) post-discontinuation. Figure 2 depicts the evolution of scaled price over time: there is no visible pre-trend before the discontinuation event, prices drop significantly one year after discontinuation and prices remained depressed for the following three years.

The result from the specification including borrower and vehicle mileage controls in the scaled price regression supports the conclusion that discontinuation reduces vehicle value, as shown in the fifth column of Table 2.

The second key feature of non-durable assets, which is highlighted in Assumption 1b in Section 2, is that they have a lower ratio of residual value to current period price. We define the recovery percent of a vehicle to be the value the lender receives from the vehicle's liquidation after default divided by the vehicle's wholesale value at origination. This is the empirical analogue of the ratio of residual value to current price.

As our second test for whether discontinuation can be viewed a negative durability shock, we regress the recovery percent on the post-discontinuation dummy and the standard fixed effects. We note here for clarity that we assign the post-discontinuation indicator to a vehicle if it is purchased after discontinuation. As we showed in Table 2, these vehicles have lower current period prices when purchased. In the present test we explore whether their future recovery values are lower, as a fraction of their already reduced prices, relative to other vehicles.

We find, as shown in the first column of Table 3, that the recovery percent is 1.07 percentage points lower (t -statistic=-2.61) for post-discontinuation vehicles. This is a meaningful drop compared to the average recovery percent of 28. In the second column of Table 3, we show that including borrower and vehicle mileage controls and a control for the time to default yields a coefficient of -1.91 percentage points (t -statistic=-5.62) on post-discontinuation. Including an additional fixed effect at the corporate parent-year of default level results in an estimated coefficient of -1.73 percentage points (t -statistic=-4.94), as shown in the third column of Table 3.

These results support the general conclusion that discontinued vehicles have lower residual values, even when viewing those residual values as a fraction of their lower current prices. The discontinuation shock is thus consistent with both components of non-durability described in Assumption 1. Discontinued vehicles have lower prices and lower residual values, and we consequently view them as less-durable assets for the purpose of testing the theoretical predictions outlined in Section 2.

5.2. *Durability and Consumer Income*

Result 1a in the theoretical framework presented in Section 2 is that high-income borrowers will purchase more durable assets. This prediction arises in both Model ABL and Model ABL+CFBL. The basic intuition is that durable assets are attractive but expensive.

We test this prediction by regressing an indicator for whether a borrower had a bottom quartile income relative to all borrowers in that year on the post-discontinuation dummy and the standard fixed effects. We find, as shown in the first column of Table 4, that discontinuation increases the probability that the purchaser is in the bottom income quartile by 3.44 percentage points (t -statistic=2.92). This finding supports Result 1a: low-income borrowers are more likely to buy the less-durable discontinued vehicles. A regression of the log of borrower income on discontinuation yields a coefficient of -0.01 (t -statistic=-1.96), as

displayed in the second column of Table 4. Discontinued vehicles are purchased by lower income borrowers, and the the effect is especially pronounced for borrowers in the bottom income quartile.

5.3. Durability and Payment-to-Income Ratios

A second shared prediction of the two models that is described in Result 1b is that the payment-to-income ratio will be lower for low-income consumers if the residual value of the non-durable asset is sufficiently low. Low-income consumers purchase the non-durable asset. The low residual value of this asset limits the amount of debt that low-income borrowers can receive, so their payment-to-income ratios are below those of the high-income borrowers who purchase durable assets with large residual values that can be financed with substantial debt.

We test this prediction by regression the log of the borrower’s payment-to-income (PTI) ratio on the post-discontinuation variable and the standard fixed effects. We find a negative and significant effect of discontinuation on the log of PTI (coefficient=-0.02 and t -statistic=-2.73), as displayed in the first column of Table 5. PTI ratios of the purchasers of these vehicles drop by 2 percent after discontinuation is announced.

Including borrower income decile fixed effects has little impact on the estimated negative and significant effect of discontinuation on PTI, as shown in the second column of Table 5. Introducing borrower and vehicle mileage controls, either with or without borrower income decile fixed effects, also yields similar estimates, as described in columns three and four of Table 5. Figure 5 shows that borrower PTI drops after discontinuation, with no visible pre-trend.

This uniform set of findings is consistent with the intuition of both Models ABL and ABL+CFBL that non-durable assets support reduced financing relative to income for their buyers.

5.4. *Durability and Loan Maturity*

The models we consider in our theoretical framework involve one period loan repayments, so they do not generate formal predictions for the impact of durability on loan maturity. It is intuitive, however, that less durable assets will be financed with shorter-term asset-backed debt, and this implication arises, for example, in the model of Hart and Moore (1994). Hart and Moore (1994) also argue that human capital cannot support long-term debt as it belongs only to its owner and may be withdrawn from use at any time. A reduction in durability that leads to greater use of cash flow-based financing should thus lead to shorter-term financing. Both asset-backed and cash flow-based models of financing therefore suggest that a decrease in asset durability will result in shorter-maturity debt.

We test this hypothesis by regressing the observed maturity in months of the auto loan on the post-discontinuation dummy and the standard fixed effects. We find that discontinuation reduces the maturity of the loan (coefficient=-0.81 and t -statistic=-5.59), as displayed in the first column of Table 6. The reduction of 0.81 months in loan maturity after discontinuation is a meaningful effect, though perhaps not very large compared to the mean loan maturity of 67.54 months. Overall, however, there is little observed variation in loan maturities (the interquartile range is 66 to 72 months), so it is notable that we find an effect of reasonable magnitude. As in Argyle et al. (2020), we find that cars with shorter expected lives receive loans with shorter maturities. Including borrower and vehicle mileage controls has little impact on the estimated coefficient, as we show in the second column of Table 6.

5.5. *Durability and LTV ratios*

The results described above in Section 5.5.1 serve to validate the use of discontinuation as a shock to durability. The results in Sections 5.5.2-5.5.4 support the shared predictions of asset-backed and joint asset-backed and cash flow-based financing models for the impact of a reduction in durability on borrower income, PTI ratios and loan maturity. In this section,

we consider the contrasting implications of Models ABL and ABL+CFBL for the effects of durability on LTV. Specifically, in Model ABL LTV increases with durability (Result 2a), while in Model ABL+CFBL LTV may decrease with durability (Result 3a).

We define the LTV to be the ratio of the loan balance to the wholesale value of the auto at the time of origination. We regress LTV on the post-discontinuation indicator and the standard fixed effects, and we find a positive and significant coefficient of 0.02 (t -statistic=3.62), as displayed in the first column of Table 7. This result shows that a discontinuation shock reducing vehicle durability leads to higher LTV ratios, which can arise in Model ABL+CFBL.

It is a general and robust feature of models of asset-backed financing that LTV increases with durability—we find this implication in our Model ABL, as well as in Hart and Moore (1994) and Rampini (2019). When the asset constitutes the entire collateral, more durable assets with higher liquidation values support larger loans relative to current values. Our finding to the contrary indicates that in the auto loan market, cash flow-based lending must play an important role. Model ABL+CFBL describe a setting in which borrowers can rely on their future income to purchase assets. Low-income borrowers, in particular, use their future income to purchase non-durable assets. If the price of the non-durable asset is relatively low, then low income borrowers will purchase it with a relatively high debt ratio, as the debt is secured by their incomes, not by the physical collateral. This mechanism in Model ABL+CFBL is consistent with the finding that LTV *increases* after a decline in durability.

Including borrower and vehicle mileage controls has little impact on the estimated effect of the discontinuation shock on LTV (coefficient=0.02 and t -statistic=5.63). The general conclusion is unchanged: less durable autos are financed with higher LTV ratios, which emerges as a potential outcome in Model ABL+CFBL but not in Model ABL.

We further comment that the mean (and median) LTV for our auto borrowers is 129%. In the ABL model this high level of debt would be unexpected, as lenders can only seek repayment from the asset value. LTVs of above 100% can be supported, however, in the

ABL+CFBL model as the borrowers' future income is also used to meet the required debt payments.

5.6. *Durability and Down Payments*

Models ABL and ABL+CFBL also offer conflicting predictions for the impact of durability on the dollar value of the borrower's down payment (i.e., the cash amount paid by the borrower on the transaction date). In Model ABL, durable assets require larger down payments (Result 2b), while in Model ABL+CFBL non-durable assets may be purchased with bigger down payments (Result 3b).

We regress the down payment on the post-discontinuation indicator and the standard fixed effects. We find that discontinuation leads to larger down payments, as displayed in the first column of Table 8. Consistent with the mechanism in Model ABL+CFBL, borrowers supply an additional \$86.1 (t -statistic=3.84) in down payments when purchasing non-durable discontinued vehicles. As shown in Figure 4, down payments climb significantly after discontinuation and do not exhibit any apparent pre-trend.

This down payment result is particularly surprising from the perspective of a model with only physical collateral like Model ABL. We showed above in Table 2 that discontinued vehicles are less expensive. This fact, along with the limited pledgeability of collateral emphasized in asset-backed models of lending, should lead discontinued autos to require lower down payments. Moreover, we demonstrate in Table 4 that these vehicles are purchased by lower-income borrowers who presumably have less cash in hand for a down payment. Despite these two compelling intuitions underlying Model ABL's prediction of lower down payments for non-durable assets, we find the opposite. Model ABL+CFBL explains that cash flow-based lending is an important feature of auto lending, and low-income consumers have smaller future incomes against which to borrow. As a consequence, the low-income purchasers of non-durable assets may need to provide larger down payments to close the transactions.

The positive impact of discontinuation on down payments continues to hold when controlling for borrower and vehicle mileage fixed effects, as detailed in the second column of Table 8. We show in the third column of Table 8 that in the cross-section more expensive vehicles with elevated book values generally require higher down payments. There are, however, many unobserved differences between vehicles of different prices. Our result that discontinuation shocks lead to higher down payments on vehicles of specific model-vintage years is somewhat stronger when controlling for this vehicle book value effect, as is displayed in the third column.

5.7. Durability and Recovery in Default

Our tests linking discontinuations to higher LTVs and down payments are consistent with Model ABL+CFBL. The key distinction, however, between Models ABL and ABL+CFBL is that consumers in Model ABL+CFBL are able to borrow against their future income and need not rely solely on the physical asset to serve as collateral. In this section we discuss the evidence on post-default lender collections. In particular, is it the case that lenders actually take recovery from the personal resources of borrowers?

We have data on the recovery proceeds from 79,012 defaulted loans. For many of these loans, the recovery is still in process at the close of our sample. Eliminating those censored observations leaves 38,183 defaulted loans with complete recovery information. For this sample, we find that the average proceeds from the sales of repossessed vehicles are \$3,722. The average cash recovery from the borrower is \$1,827. We thus find that in default physical assets and personal borrower resources supply 67% and 33%, respectively, of the total recovery proceeds. These summary statistics show that in the auto loan market, a market in which vehicle collateral is generally deemed to serve a central role, borrower personal income pledges do perform a significant function.

5.8. *Cash flow-based Lending to Low-Income Consumers—Default Recoveries*

The results in Tables 7 and 8 showing that a reduction in durability leads to higher LTVs and larger down payments demonstrate that income-based lending is important in the auto financing market. As outlined in the ABL+CFBL Model Implication in Section 2, these empirical findings also establish that low-income borrowers rely more heavily than high-income borrowers on CFBL

The vehicle default recovery data make possible an additional test of this implication. We show in Table 4 that discontinued vehicles tend to be purchased by low-income consumers. Under the ABL+CFBL Model Implication, these consumers rely relatively less on ABL and relatively more on CFBL than high-income borrowers. We should therefore expect to observe lower vehicle recoveries and higher personal income recoveries from the purchasers of discontinued vehicles who default.

We test these predictions by regressing the ratio of the vehicle recovery to the defaulted loan balance on the post-discontinuation indicator, the standard fixed effects and an additional fixed effect at the level of the corporate parent-default year to control for any time-varying effects at the level of the manufacturer. We find, as shown in the first column of Table 9, that the percentage of the loan balance recovered through liquidation of the vehicle decreases (coefficient=-3.15 and t -statistic=-2.76) after discontinuation. Less durable assets provide diminished physical recovery proceeds, as expected under both Models ABL and ABL+CFBL. Including borrower, vehicle mileage and time to default controls has little impact on the estimated coefficient on discontinuation, as detailed in the second column of Table 9.

A decrease in durability reduces not only the percent recovered from the repossessed asset but also the dollar amount. We find that discontinued vehicles are worth \$566.1 less (t -statistic=2.52) in repossession. This result is displayed in the third column of Table 9. The

result for the specification including the full set of controls, outlined in the fourth column, is quite similar.

While it is perhaps unsurprising that vehicle recoveries are lower for discontinued vehicles, it is a novel implication of Model ABL+CFBL that personal income recovery should be higher for non-durable assets. We test this hypothesis by regressing the ratio of the personal borrower payments to the defaulted loan balance on the post-discontinuation indicator and the fixed effects described above. We find, as displayed in the fifth column of Table 9, that the fraction of personal payments weakly increases (coefficient=1.59 and t -statistic=1.74) after discontinuation. A similar result holds in the specification with all the controls, as shown in the sixth column of Table 9.

The dollar amount of personal post-default payments is significantly higher after discontinuation (coefficient=244.3 and t -statistic=2.41), as we detail in the seventh column of Table 9. Including controls little alters this conclusion; the results are displayed in the eighth column of the table.

Further, we find that the probability of any post-default personal recovery is significantly higher (coefficient=5.90 and t -statistic=3.68) for discontinued vehicles, as shown in the ninth column of Table 9. This continues to hold when adding controls, as shown in the tenth column of the same table.

Taken together, these results provide convincing support for the contention of the ABL+CFBL Model Implication that low-income borrowers rely more heavily than high-income borrowers on their income as a source of collateral. It is striking that purchasers of discontinued vehicles are more likely to have their personal resources pursued by a lender after default. These consumers have lower incomes and they buy less expensive vehicles. For both of these reasons, one might have expected them to be less likely to be subject to personal recovery in the event of a default, yet we find the opposite. Model ABL+CFBL supplies the intuition for our finding: purchasers of discontinued non-durable vehicles must pledge their own income, rather than the quickly depreciating physical asset, in order to receive a loan. In the

event of default, a lender therefore will have to have recourse to their income, as the physical collateral does not have much value.

6. Discussion

6.1. *CFBL for Consumers and Firms*

The heavy dependence on CFBL by low-income borrowers that is demonstrated by the higher LTVs and down payments for discontinued vehicles, as interpreted in the context of the Model ABL+CFBL Implication, and that is highlighted in Table 9 contrasts starkly with the financing pattern in the corporate market. These low-income consumers who rely on CFBL typically have riskier repayment outcomes. Leeth and Scott (1989), John et al. (2003), Jimenez et al. (2006) and Lian and Ma (2021), by contrast, show that better-resourced firms make greater use of CFBL, while riskier and more constrained small businesses are more likely to utilize collateral and ABL. What explains this sharp divergence in the risk profiles of CFBL borrowers in the two markets? Result 3 in Section 2 makes clear that CFBL can only influence financing when income is sufficiently pledgeable. That is, lenders must have a credible claim on the income of the borrower. In the consumer lending market, this claim can take the form of wage garnishment or bankruptcy payment plan. Although defaulting consumers may be eligible for a Chapter 7 liquidation without repayment, that option carries significant long-term credit report consequences that are likely unappealing.

For small businesses, by contrast, the default and abandonment option is much less expensive. Firms can file for bankruptcy and have their corporate lives terminated. The former owners may then go on to form new companies that are unburdened in a corporate sense by the bankruptcy history of their principals' previous ventures. The accessibility of this abandonment option for small firms makes their future cash flows less pledgeable and necessitates their reliance on ABL. For large corporations with ongoing business operations,

the abandonment possibility is less of a concern, and lenders are therefore willing to supply them with CFBL.

6.2. *Trends in Consumer CFBL financing*

The dependence by low-income borrowers on CFBL suggests that recent changes in securitization markets have potentially broad implications for the relative auto credit access of poor consumers. Specifically, Figure 7 displays total annual securitization issuances for autos, equipment, student loans, and credit cards. As is clear from the figure, in the post-financial crisis period (i.e., since 2008) there has been a significant increase in the securitization of ABL financing such as equipment relative to CFBL financing such as student loans and credit cards. One possible rationale for this shift is that it became apparent during the financial crisis that monitoring incentives were reduced for securitized debt (Keys et al., 2010), and such monitoring is likely more important for CFBL than for ABL. A second candidate explanation is that post-crisis Basel III risk weightings of bank loans adjusted to favor collateralized assets (Degryse et al., 2021), which may have led to both reduced originations and decreased securitizations of CFBL. Irrespective of the underlying cause, we argue that this change in securitization is important for auto financing, which, our study argues, is a composite of ABL and CFBL.

In particular, a rise in ABL securitization relative to that of CFBL is likely to facilitate the availability of the former type of financing at lower prices. Given the importance of the CFBL component of auto debt to low-income borrowers, this suggests that an increasing fraction of vehicle lending will be directed to wealthier consumers. To explore the effects of changing market conditions, we examine the relationship between auto financing of consumers and the securitization of ABL relative to securitization of CFBL. Specifically, each year we calculate the ratio of securitized equipment lending, which is almost entirely ABL, to the ratio of the sum of equipment, credit card, and student loan lending, where the latter two are almost

entirely CFBL.⁷ We then plot the relationship across the highest and lowest income quartiles since the onset of the financial crisis in Figure 8.⁸ As the ratio of equipment to total securitization increases, borrowers in the highest income quartile experience an increase in auto financing, while borrowers in the lowest income quartile experience a decrease. Although this figure depicts an association rather than a necessarily causal connection, it is consistent with the argument that the importance to low-income borrowers of CFBL, which has been relatively disfavored by securitization markets, may be acting to reduce their ability to purchase vehicles.

The U.S. government devotes significant resources to facilitating access to mortgage financing for less-wealthy citizens. Studies of home mortgages have emphasized the role of borrower income (i.e., CFBL) in influencing the terms and performance of lending (Archer et al., 1996; Diaz-Serrano, 2005; Piskorski and Tchisty, 2010), though there is evidence that reported incomes are sometimes misstated (Blackburn and Vermilyea, 2012; Jiang et al., 2014; Ambrose et al., 2016; Mian and Sufi, 2017). CFBL should be expected to serve an even more important function in the auto lending market in which the asset depreciates quite quickly.

Vehicles play an important role in helping consumers access jobs and achieve mobility, and their prices have recently been increasing.⁹ Restricted credit access for low-income borrowers arising from their reliance on CFBL may narrow their prospects. Financially constrained car purchasers receive no federal auto financing assistance, despite the darkening credit conditions for these consumers and the crucial role cars play in creating opportunity.

⁷To avoid any mechanical relationship, we exclude securitized auto lending.

⁸We present the regression underlying this analysis in the internet appendix.

7. Conclusion

We study the roles of asset-backed lending (ABL) and cash flow-based lending (CFBL) in the U.S. auto financing market. Using a simple theoretical framework, we show that ABL-only and ABL+CFBL models make differing predictions for the effects of a reduction in asset durability; less durable assets have lower LTV ratios and down payments in the ABL model and may have higher LTV ratios and down payments in the ABL+CFBL model. In our empirical analysis, we show that model and make discontinuations generate a negative durability shock for used cars: post-discontinuation, holding fixed the model-vintage year, we observe that discontinued vehicles have lower prices, lower liquidations values and are purchased by lower-income consumers.

After discontinuation, LTV ratios increase by about two percentage points and down payments are higher by approximately \$92. These two findings support an ABL+CFBL model of the auto market in which low-income borrowers rely relatively more heavily on CFBL. In a sample of defaulted loans, we find that roughly two-thirds of lender recoveries arise from the vehicle (which serves as the collateral in the ABL model) and the remaining one-third comes from the borrower personally (the source of the guarantee in the CFBL model). Post-discontinuation physical collateral recoveries are \$585 lower and personal default recoveries increase by \$287. The higher personal recoveries on discontinued vehicles may seem surprising given that their purchasers have lower incomes and buy less-expensive vehicles. The ABL+CFBL model supplies the intuition that low-income borrowers make greater use of CFBL and must therefore use their personal resources, rather than the collateral value of the vehicle, to cover missing payments in the event of default.

In the post-financial crisis period, securitization market issuances have increased relatively more for ABL than for CFBL forms of financing. This shift may limit relative credit access for the lower-income borrowers who rely on CFBL. A resulting restriction on the ability of less-wealthy consumers to purchase cars may have wide-ranging implications for

their welfare. Our results indicate that innovations that aid lenders in monitoring borrower incomes are likely to be especially helpful for constrained consumers who seek auto financing.

Figure 1: **Total Motor Vehicle Outstanding.** This figure presents the quarterly total motor vehicle loans owned and securitized in the United States. All amounts are billions of U.S. Dollars. All data is from Board of Governors of the Federal Reserve System (US), Motor Vehicle Loans Owned and Securitized [MVLOAS], retrieved from FRED, Federal Reserve Bank of St. Louis; <https://fred.stlouisfed.org/series/MVLOAS>, November 5, 2021.

Figure 2: **Scaled Price against Event Time.** This figure presents differences in the scaled price across vehicles (models & makes) that were discontinued and those that were not. The plot is the regression coefficients for timing indicators around the year the model was discontinued (discontinuation year=0). The dependent variables is the book value of the vehicle divided by the average book value when new, as reported to the lender when new. Included fixed effects are Make/Model x Vintage Year, Dealership, and Contract Year x Parent Company.

Figure 3: **LTV against Event Time.** This figure presents differences in the loan to value (LTV) across vehicles (models & makes) that were discontinued and those that were not. The plot is the regression coefficients for timing indicators around the year the model was discontinued (discontinuation year=0). The dependent variables is the loan amount divided by the reported vehicle value to the lender for the vehicle. Included fixed effects are Make/Model x Vintage Year, Dealership, and Contract Year x Parent Company.

Figure 4: **Down Payment against Event Time.** This figure presents differences in the down payments across vehicles (models & makes) that were discontinued and those that were not. The plot is the regression coefficients for timing indicators around the year the model was discontinued (discontinuation year=0). The dependent variables is the winsorized down payment for the vehicle. Included fixed effects are Make/Model x Vintage Year, Dealership, and Contract Year x Parent Company.

Figure 5: **PTI against Event Time.** This figure presents differences in the log of the payment to income ratio (PTI) across vehicles (models & makes) that were discontinued and those that were not. The plot is the regression coefficients for timing indicators around the year the model was discontinued (discontinuation year=0). The dependent variables is the log of the borrowers reported monthly payment to the borrower's reported monthly income reported vehicle value to the lender for the vehicle. Included fixed effects are Make/Model x Vintage Year, Dealership, borrower income decile, and Contract Year x Parent Company.

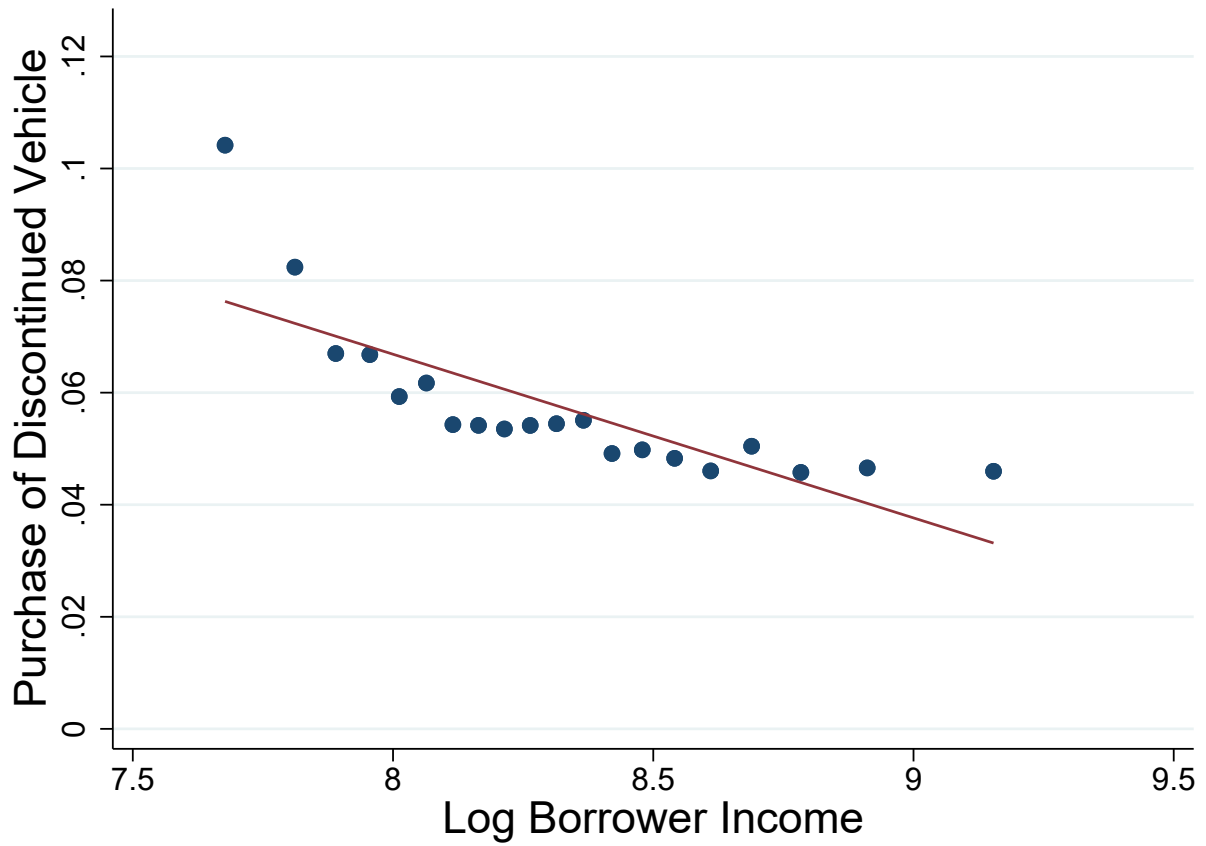

Figure 6: **Purchase of Discontinued Vehicle (=1) against Borrower Income.** This figure presents the average propensity for the borrower of a given log income bucket (20 buckets) to purchase a discontinued vehicle.

Figure 7: **US Asset Backed Securitization** This figure presents the total annual issuance of US Asset Backed Securities in the United States for four categories (auto, equipment, student loans, and credit cards). All amounts are billions of U.S. Dollars. All data is from Bloomberg, Dealogic, Thomson Reuters; www.sifma.org, March 28 2022.

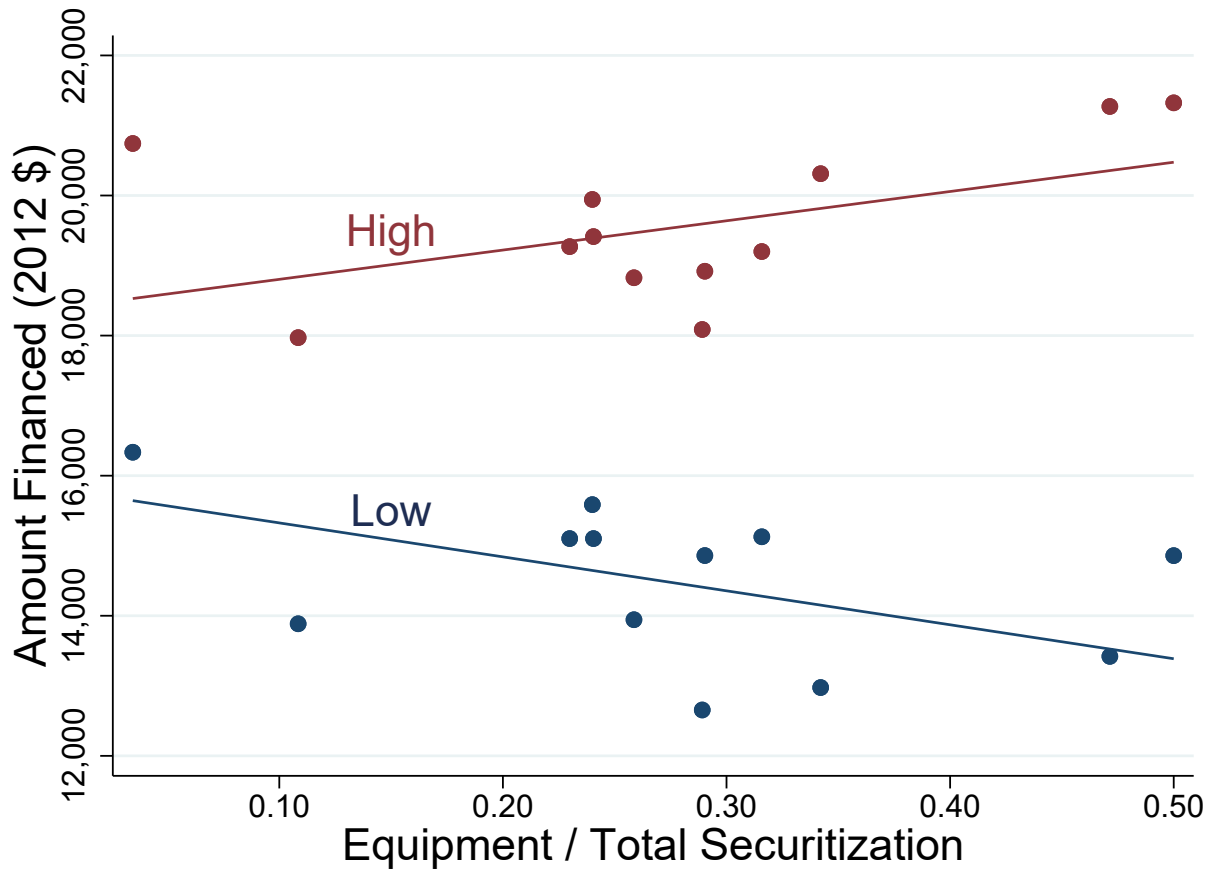

Figure 8: **Amount Financed to Asset Based Securitization.** This figure presents the average amount financed for borrowers for a given bucket of the ratio of equipment based securitization over the sum of credit card, student loan, and equipment based securitization across the lowest and highest borrower income quartiles based on the year of the transaction from 2008 to 2021. Amount financed is deflated to 2012 dollars using the GDP deflator from the St. Louis Federal Reserve. All data securitization data is from Bloomberg, Dealogic, Thomson Reuters; www.sifma.org, March 28 2022.

Table 1: **Summary Statistics.** This table reports summary statistics for the variables used in the analysis. *Post-Discontinuation* is an indicator for all years after the transaction year for which the brand or model of the vehicle was discontinued. *Vehicle Book Value* is the vehicle’s wholesale value at the time of the sale. *Vehicle Mileage* is the vehicle’s mileage at origination. *Vehicle Residual Value* is the ratio of the vehicle’s value at origination to the average value of the vehicle’s make, model, and vintage when new (new=100). *Down Payment* is the cash amount that the borrower paid at loan origination. *LTV* is the dollar amount of the loan at origination relative to the vehicle book value. *Predicted APR* based on borrower attributes (in % terms). *Original APR* is the actual annualized APR of the loan at origination (in % terms). *Loan Term* is the term of the loan (in months) at origination. *Log Payment-to-Income* ratio (PTI) is the log of the borrower’s estimated monthly payment over the borrower’s reported monthly income. *Low Income* is an indicator if the borrower is in the lowest income quartile for the transaction year. *Monthly Income* is the gross monthly income for the borrower. *Credit Score* is the credit score of the borrower. *Default Indicator* is an indicator variable if the borrower eventually defaults. *Ch. 7 Bankruptcy* and *Ch. 13 Bankruptcy* are indicators if the borrower had a bankruptcy on their record prior to origination. *Homeowner* is an indicator if the borrower owned their home. All continuous variables are winsorized at the 1st and 99th percentile.

Table 2: **Vehicle Book Value and Vehicle Discontinuation.** This table reports estimates from panel regressions of the vehicle's reported value on model discontinuation. In columns (1) to (3), the dependent variable is the vehicle *Book Value*, the wholesale value of the vehicle reported to the lender at loan origination. In columns (4) and (5), the dependent variable is the vehicle's *scaled price*, the vehicle whole sale value reported to the lender at origination over the average of the given vehicle model and year wholesale value when new. *Post-Discontinuation* is an indicator for all years after the transaction year for which the brand or model of the vehicle was discontinued. *Income* is the log of the gross monthly income for the borrower. *Credit Score* is the credit score of the borrower. *Ch. 7 Bankruptcy* and *Ch. 13 Bankruptcy* are indicators if the borrower had a bankruptcy on their record prior to origination. *Homeowner* is an indicator if the borrower owned their home at origination. *Log Mileage* is the log of one plus the vehicle's mileage at origination. Fixed effects are as described in the table. Parent fixed effects relate to the parent company of the make and model. Robust standard errors are clustered by vehicle make. The t-statistics are shown in parentheses below the coefficient estimates. *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Table 3: Default Recovery and Vehicle Discontinuation. This table reports estimates from panel regressions of proxies of the vehicle’s residual value. The dependent variable is the *Percent recovery* of the lender conditional on default. It is value the lender receives from the vehicle liquidation after default over the vehicle’s wholesale value at origination. All observations are conditional on default and non-zero recovery. Column (3) contains fixed effects for both the year of the transaction as well as the year of the default interacted with the parent company of the vehicle. *Post-Discontinuation* is an indicator for all years after the transaction year for which the brand or model of the vehicle was discontinued. *Income* is the log of the gross monthly income for the borrower. *Credit Score* is the credit score of the borrower. *Ch. 7 Bankruptcy* and *Ch. 13 Bankruptcy* are indicators if the borrower had a bankruptcy on their record prior to origination. *Homeowner* is an indicator if the borrower owned their home at origination. *Log Mileage* is the log of one plus the vehicle’s mileage at origination. *Time to Default* is the time (in months) between the transaction and the report of default. Fixed effects are as described in the table. Parent fixed effects relate to the parent company of the make and model. Robust standard errors are clustered by vehicle make. The t-statistics are shown in parentheses below the coefficient estimates. *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Table 4: **Borrower Income and Vehicle Discontinuation.** This table reports estimates from panel regressions of borrower income. The dependent variable in column (1) is *Low Income* = 1 an indicator for whether the borrower was in the bottom quartile of income for borrowers in that year. The dependent variable in column (2) is the *Log Income* of the borrower reported to the lender at the time of the origination. *Post Discontinuation* is an indicator for all years after the transaction year for which the brand or model of the vehicle was discontinued. Fixed effects are as described in the table. Parent fixed effects relate to the parent company of the make and model. Robust standard errors are clustered by vehicle make. The t-statistics are shown in parentheses below the coefficient estimates. *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Table 5: **Payment to Income (PTI) and Vehicle Discontinuation.** This table reports estimates from panel regressions of the payment to income ratio of the borrower. The dependent variable is the natural log of the *Payment-to-Income* ratio (PTI), which is borrowers estimated monthly payment over the borrower's reported monthly income. *Post Discontinuation* is an indicator for all years after the transaction year for which the brand or model of the vehicle was discontinued. *Income* is the log of the gross monthly income for the borrower. *Credit Score* is the credit score of the borrower. *Ch. 7 Bankruptcy* and *Ch. 13 Bankruptcy* are indicators if the borrower had a bankruptcy on their record prior to origination. *Homeowner* is an indicator if the borrower owned their home at origination. *Log Mileage* is the log of one plus the vehicle's mileage at origination. Fixed effects are as described in the table. Parent fixed effects relate to the parent company of the make and model. Income decile fixed effects are indicators for the borrower's income decile in the transaction year. Robust standard errors are clustered by vehicle make. The t-statistics are shown in parentheses below the coefficient estimates. *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Table 6: Loan Maturity and Vehicle Discontinuation. This table reports estimates from panel regressions of the maturity of the loan at origination. The dependent variable *Loan Maturity* is the original maturity of the loan at origination (in months). *Post Discontinuation* is an indicator for all years after the transaction year for which the brand or model of the vehicle was discontinued. *Income* is the log of the gross monthly income for the borrower. *Credit Score* is the credit score of the borrower. *Ch. 7 Bankruptcy* and *Ch. 13 Bankruptcy* are indicators if the borrower had a bankruptcy on their record prior to origination. *Homeowner* is an indicator if the borrower owned their home at origination. *Log Mileage* is the log of one plus the vehicle’s mileage at origination. Fixed effects are as described in the table. Parent fixed effects relate to the parent company of the make and model. Robust standard errors are clustered by vehicle make. The t-statistics are shown in parentheses below the coefficient estimates. *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Table 7: **Loan to Value (LTV) and Vehicle Discontinuation.** This table reports estimates from panel regressions of the loan to value (LTV) ratio. The dependent variable in columns (1) to (3) is the *Loan-to-Value* (LTV) ratio, which is the amount financed over the reported wholesale vehicle book value. *Post Discontinuation* is an indicator for all years after the transaction year for which the brand or model of the vehicle was discontinued. *Income* is the log of the gross monthly income for the borrower. *Credit Score* is the credit score of the borrower. *Ch. 7 Bankruptcy* and *Ch. 13 Bankruptcy* are indicators if the borrower had a bankruptcy on their record prior to origination. *Homeowner* is an indicator if the borrower owned their home at origination. *Log Mileage* is the log of one plus the vehicle's mileage at origination. Fixed effects are as described in the table. Parent fixed effects relate to the parent company of the make and model. Robust standard errors are clustered by vehicle make. The t-statistics are shown in parentheses below the coefficient estimates. *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Table 8: **Down payment and Vehicle Discontinuation.** This table reports estimates from panel regressions of the vehicle's down payment at origination. The dependent variable is the winsorized vehicle's *Down Payment*, the cash amount that the borrower pays at loan origination. *Post Discontinuation* is an indicator for all years after the transaction year for which the brand or model of the vehicle was discontinued. *Vehicle Value* is the vehicle's value to the loan provider at sale. *Income* is the log of the gross monthly income for the borrower. *Credit Score* is the credit score of the borrower. *Ch. 7 Bankruptcy* and *Ch. 13 Bankruptcy* are indicators if the borrower had a bankruptcy on their record prior to origination. *Homeowner* is an indicator if the borrower owned their home at origination. *Log Mileage* is the log of one plus the vehicle's mileage at origination. Fixed effects are as described in the table. Parent fixed effects relate to the parent company of the make and model. Robust standard errors are clustered by vehicle make. The t-statistics are shown in parentheses below the coefficient estimates. *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Table 9: Recovery and Vehicle Discontinuation. This table reports estimates from panel regressions of the recovery on defaulted loans. The dependent variable is the: percent of the balance of a defaulted loan recovered via repossession of the vehicle net of fees (columns (1) and (2)); dollar value of the recovered vehicle net of fees (columns (3) and (4)); percent of the balance of a defaulted loan recovered via the income of the borrower net of fees (columns (5) and (6)); dollar value of the income recovery amount net of fees (columns (7) and (8)); and an indicator (=1) if there was any positive income recovery, coefficients are multiplied by 100 for exposition (columns (9) and (10)). *Post-Discontinuation* is an indicator for all years after the transaction year for which the brand or model of the vehicle was discontinued. *Income* is the log of the gross monthly income for the borrower. *Credit Score* is the credit score of the borrower. *Ch. 7 Bankruptcy* and *Ch. 13 Bankruptcy* are indicators if the borrower had a bankruptcy on their record prior to origination. *Homeowner* is an indicator if the borrower owned their home at origination. *Log Mileage* is the log of one plus the vehicle's mileage at origination. *Time to Default* is the time (in months) between the transaction and the report of default. Fixed effects are as described in the table. Parent fixed effects relate to the parent company of the make and model. Robust standard errors are clustered by vehicle make. The t-statistics are shown in parentheses below the coefficient estimates. *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Table IA.3: Amount Financing relative to Asset Based Securitization. This table reports estimates from panel regressions of the amount financing. In columns (1) and (3), the dependent variable is the amount financed by the borrower. In columns (2) and (4), the dependent variable is the log of the amount financed. *Eq/Total* is the dollar value of securitization of equipment loans over the total of credit card, student, and equipment loan securitization. *Q2 Income*, *Q3 Income*, *Q4 Income* are indicators for the 2nd, 3rd, and 4th quartiles of income for the borrower in the year of the vehicle purchase. *Log Borrower Income* is the log of the monthly borrower income. *Post-Crisis* is an indicator =1 if the transaction took place after 2010. The sample period begins in 2003. Robust standard errors are clustered by transaction year. The t-statistics are shown in parentheses below the coefficient estimates. *, **, and *** indicate statistical significance at the 10%, 5%, and 1% levels, respectively.

Appendix A. Theoretical Setup

To illustrate the effects of a durability shock on the consumer financing of asset purchases, we provide a simple model of financing. The key difference between our model and others that examine the effects of durability (e.g., Rampini, 2019), is that we allow for both asset based lending (ABL) as well as cash flow based lending (CFBL). We show that the addition of a sufficient level of CFBL is central to explaining our empirical results. The model consists of two-periods and three agents (consumers, sellers, and lenders). All agents are risk neutral.

Appendix 1.1. Consumers and Goods

There are two types (low and high) of consumers $i \in \{L, H\}$. Both consumer types have income in each period, but differ in the level of their incomes, where $I_H > I_L > 0$. We further assume that the difference in incomes is not too large, so $2I_L > I_H$. Consumers can purchase one of two types of goods $G \in D, ND$, which we denote durable and non-durable. Durable goods have value $2\gamma > 0$ in the first period if resold, and value γ in the second period. Non-durable goods have value $(1 + \delta)\gamma$ in the first period and value $\delta\gamma$ in the second period, where $\delta \in (0, 1)$ represents the depreciation of the non-durable good. The only difference between the goods is their degree of depreciation. The seller (e.g., a car dealership) of the good earns some profit κ on the sale, meaning the combined price of a good is κ plus its resale value.

Consumers face no shocks, information is full, and consumers prefer current consumption over delayed consumption. Note the latter assumption is valid if, for example, the lender is more patient than the consumer or if the lender has more diversified income. Moreover, both consumer types would always prefer the more durable good if they can afford it. This assumption holds if the consumer gets the same marginal utility from each good, meaning the benefit is relatively cheaper given the fixed margin κ that the seller of the asset charges. We further presume that purchasing the non-durable good is attractive relative to purchasing nothing, even accounting for consumers' subjective preference for first period consumption.

Appendix 1.2. Pledgeability of Physical and Human Capital

Consumers can borrow from a competitive set of lenders to finance their purchase. As in Rampini (2019), due to the limited pledgeability of assets, lenders require collateral. The consumer can pledge the goods' value in the second period (i.e., ABL) as well as their income in the second period (i.e., CFBL). The pledgeability of physical and human capital is denoted by $\{\theta_G, \theta_I\}$, where both are bounded between $[0, 1)$, which represent the fraction of the asset and income, respectively, that can be pledged as collateral. For simplicity, we assume that the risk-free rate is 0. Consumers face no sanction or cost from defaulting other than the loss of any pledged income or the good.

To examine the interesting parameter space of the model, we assume that high (low)-income consumers can (cannot) afford the durable good if they borrow their maximum feasible limit:

$$\theta_I I_L + \theta_G \gamma + I_L < 2\gamma + \kappa < \theta_I I_H + \theta_G \gamma + I_H. \quad (\text{A1})$$

Low income consumers, however, can afford the non-durable good even without pledging their income.

$$\theta_G \delta \gamma + I_L > (1 + \delta)\gamma + \kappa. \quad (\text{A2})$$

We assume that κ is such that equations A1 and A2 hold

Appendix 1.3. Analysis

We now solve for the loan characteristics of low income and high income consumers. Specifically, we examine the (1) down payments, (2) loan-to-value ratios, and (3) payment-to-income ratios of the two types of consumers under the two lending regimes (i.e., ABL and CFBL). First, for each metric we examine the characteristic assuming that only ABL is available (i.e., if $\theta_I = 0$). We then solve for the characteristic allowing for both ABL and CFBL.

Appendix 1.3.1. Down Payments

Given the pledgeability constraints and the markup, consumers need to pay for some portion of the good in period 1 using their first period income I_i . Under the assumption that consumers prefer to maximize first period consumption, the consumer will seek to minimize their down payment and maximize their borrowing. First, we examine the case with only ABL (i.e., $\theta_I = 0$). The down payment for the consumer who purchases the durable good is

$$\kappa + 2\gamma - \gamma\theta_g. \quad (\text{A3})$$

The down payment for the consumer who purchases the non-durable good is

$$\kappa + (1 + \delta)\gamma - \gamma\delta\theta_g. \quad (\text{A4})$$

The down payment is higher for the durable good since $\delta \in (0, 1)$. However, note that low income consumers cannot afford the durable good. Therefore, low income consumers purchase the non-durable good and have a lower down payment. This matches the result in Rampini (2019) that non-durable goods have lower down payments and are purchased by financially constrained (low-income) buyers.

Next, we examine the case when both ABL and CFBL ($\theta_I > 0$) are available. The down payment for the consumer who purchases the durable good is

$$\kappa + 2\gamma - \gamma\theta_g - I_i\theta_I. \quad (\text{A5})$$

The down payment for the consumer who purchases the non-durable good is

$$\kappa + (1 + \delta)\gamma - \gamma\delta\theta_g - I_i\theta_I. \quad (\text{A6})$$

If income is sufficiently pledgeable, specifically if

$$\theta_I > \frac{\gamma(1 - \delta)(1 - \theta_g)}{I_H - I_L}, \quad (\text{A7})$$

then the down payment is greater for the non-durable goods. This condition states that the income pledgeability constraint weakens when the difference between the non-pledgeable value of the assets is smaller than the difference in the borrower incomes.

The intuition is that if the depreciation is too small, then the *price effect* (i.e., the lower price and down payment from the difference in depreciation) will dominate the *income pledgeability effect* (i.e., lower income supporting smaller cash flow based loan and therefore a higher down payment).

Appendix 1.3.2. Loan-to-Value (LTV) Ratio

We now turn to the loan-to-value (LTV) ratios. The collateral value of the durable and non-durable good to the lender is 2γ or $(1 + \delta)\gamma$. With only ABL available ($\theta_I = 0$), the LTV for durable goods is

$$\frac{\gamma\theta_g}{2\gamma}. \quad (\text{A8})$$

The LTV for non-durable goods is

$$\frac{\gamma\delta\theta_g}{(1 + \delta)\gamma}. \quad (\text{A9})$$

Therefore, the LTV is always higher for the durable asset since $\delta \in (0, 1)$.

Next, we examine the case when both ABL and CFBL are available. The LTV for the high-income consumer who purchases the durable good is

$$\frac{\gamma\theta_g + I_H\theta_I}{2\gamma}. \quad (\text{A10})$$

The LTV for the low-income consumer who purchases the non-durable good is

$$\frac{\gamma\delta\theta_g + I_L\theta_I}{(1 + \delta)\gamma}. \quad (\text{A11})$$

If income is sufficiently pledgeable, specifically if

$$\theta_I > \frac{\gamma(1 - \delta)\theta_G}{2I_L - (1 + \delta)I_H}, \quad (\text{A12})$$

and if low-income borrowers are more dependent on cash flow based lending, specifically if

$$\delta < \frac{I_L}{I_H}, \quad (\text{A13})$$

then the LTV is higher for the non-durable good. The intuition for the first restriction is that the difference in incomes cannot be too large relative to the pledgeable portion of the assets. The intuition, for the second condition is that the cash flow portion of the financing must be more important for the low-income borrower. If the second condition is violated, then the pledgeability constraint would be negative for the LTV to be higher for the non-durable good. Thus, both constraints are necessary conditions for the LTV to be higher for the non-durable good.

The existence of constraints on both the pledgeability of income and the importance of the cash flow based lending provide key implications for empirical tests. Specifically, if less durable goods have lower LTVs and are purchased by lower-income consumers, then a key implication of the model is that the lower-income consumers are more dependent on cash flow based lending.

Appendix 1.3.3. Payment-to-Income (PTI) Ratio

The payment to income ratio is always lower for the low-income purchaser as long as the low-income purchases is more dependent on cash flow based lending, which is satisfied by equation A13 above. It does not depend on the type of lending.¹⁰

The overall restrictions for δ and θ_I for the down payment, LTV, and PTI results are then

$$1 > \theta_I > \max \left\{ \frac{\gamma(1-\delta)(1-\theta_g)}{I_H - I_L}, \frac{\gamma(1-\delta)\theta_G}{2I_L - (1+\delta)I_H} \right\} \quad (\text{A14})$$

$$0 < \delta < \frac{I_L}{I_H}. \quad (\text{A15})$$

¹⁰Note that the payment to income ratio for both types of consumers will be higher with CFBL, but that since income is in the numerator and denominator of the ratio, the relative level of PTI only depends on the degree of depreciation relative to the ratio of incomes.
